

INSY7311 - ICE TASK 01

Smart Campus Support App

1. The university is trying to improve the accessibility of information, notifications and systems across one platform instead of multiple methods of allowing access to information; by creating this all-inclusive app, it reduces the current issues students are facing
2. Users: - University Students
 - Lecturers
3. Without understanding the problem space, creating the app could be redundant because key features and improvements wouldn't be identified and won't make a difference to the students' current systems. To understand the problem areas before getting into creating the app, is important because it gives developers time to brainstorm ideas, gather and collect feedback from students using questionnaires/forms to find out what is most accessible and easier and use their feedback in the design/functionality process of the app first.
4. Challenges: - Missed notifications
 - Multiple systems carrying information making it confusing
5. Goals: - Easier & quicker access to notifications
 - Support systems are readily available on the new app, making it easier for new/current users to manoeuvre without being overwhelmed
6. A user-centered approach helps with the development of the app by involving users' feedback, so issues are easily picked up, optimising features preferable to the users. It also saves time and avoids extensive app redesign and allows it to remain distinctive.

7. Gather user (students/lecturers etc) feedback via surveys to validate ideas before development

8. By doing so, it fails to solve the issues of the users, because due to excessive design elements, complex navigation, and animations can clutter screens and hinder functionality and can still drive users away.
